Benny Pinkas

Based on slides of Yehuda Lindell

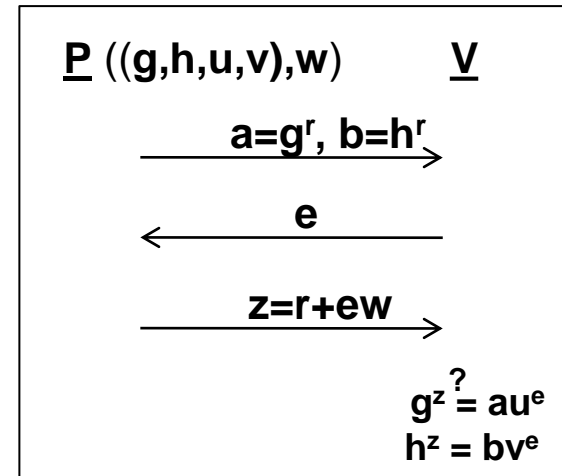

# Sigma Protocol for proving a DH Tuple

---

- ▶ Relation  $R$  of Diffie-Hellman tuples
  - ▶  $(g, h, u, v) \in R$  iff there exists  $w$  s.t.  $u = g^w$  and  $v = h^w$
  - ▶ Useful in many protocols
- ▶ This is a proof of membership, not of knowledge
  
- ▶ Protocol
  - ▶  $P$  chooses a random  $r$  and sends  $a = g^r$ ,  $b = h^r$
  - ▶  $V$  sends a random  $e$
  - ▶  $P$  sends  $z = r + ew \pmod q$
  - ▶  $V$  checks that  $g^z = au^e$ ,  $h^z = bv^e$

# Sigma Protocol DH Tuple

- ▶ **Completeness:** as in DLOG
- ▶ **Special soundness:**
  - ▶ Given  $(a,b,e,z), (a,b,e',z')$ , we have  $g^z=au^e, g^{z'}=au^{e'}, h^z=bv^e, h^{z'}=bv^{e'}$  and so like in DLOG on both
    - ▶  $w = (z-z')/(e-e')$
- ▶ **Special HVZK**
  - ▶ Given  $(g,h,u,v)$  and  $e$ , choose random  $z$  and compute
    - ▶  $a = g^z u^{-e}$
    - ▶  $b = h^z v^{-e}$

# Tools for Sigma Protocols

---

- ▶ Prove compound statements
  - ▶ AND, OR, subset
- ▶ ZK from sigma protocols
  - ▶ Can first make a compound sigma protocol and then compile it
- ▶ ZKPOK from sigma protocols

# AND of Sigma Protocols

---

- ▶ To prove the AND of multiple statements
  - ▶ Run all in parallel
  - ▶ Can use the same verifier challenge  $e$  in all
- ▶ Sometimes it is possible to do better than this
  - ▶ Statements can be batched
  - ▶ E.g. proving that many tuples are DDH can be done in much less time than running all proofs independently
    - ▶ Batch all into one tuple and prove

# OR of Sigma Protocols

---

- ▶ This is more complicated
  - ▶ Given two statements and two appropriate Sigma protocols, wish to prove that at least one is true, without revealing which
- ▶ The solution – an ingenious idea from [CDS]
  - ▶ Using the simulator, if  $e$  is known ahead of time it is possible to cheat
  - ▶ We construct a protocol where the prover can cheat in one out of the two proofs

# OR of Sigma Protocols

---

- ▶ The template for proving  $x_0$  or  $x_1$ :
  - ▶ **P** sends two first messages  $(\mathbf{a}_0, \mathbf{a}_1)$
  - ▶ **V** sends a single challenge  $\mathbf{e}$
  
  - ▶ **P** replies with
    - ▶ Two challenges  $\mathbf{e}_0, \mathbf{e}_1$  s.t.  $\mathbf{e}_0 \oplus \mathbf{e}_1 = \mathbf{e}$
    - ▶ Two final messages  $\mathbf{z}_0, \mathbf{z}_1$
  
  - ▶ **V** accepts if  $\mathbf{e}_0 \oplus \mathbf{e}_1 = \mathbf{e}$  and  $(\mathbf{a}_0, \mathbf{e}_0, \mathbf{z}_0), (\mathbf{a}_1, \mathbf{e}_1, \mathbf{z}_1)$  are both accepting
  
- ▶ How does this work?

# OR of Sigma Protocols

---

- ▶ **P** sends two first messages  $(\mathbf{a}_0, \mathbf{a}_1)$ 
  - ▶ Suppose that **P** has a witness for  $\mathbf{x}_0$  (but not for  $\mathbf{x}_1$ )
  - ▶ **P** chooses a random  $\mathbf{e}_1$  and runs SIM to get  $(\mathbf{a}_1, \mathbf{e}_1, \mathbf{z}_1)$
  - ▶ **P** sends  $(\mathbf{a}_0, \mathbf{a}_1)$
- ▶ **V** sends a single challenge  $\mathbf{e}$
- ▶ **P** replies with  $\mathbf{e}_0, \mathbf{e}_1$  s.t.  $\mathbf{e}_0 \oplus \mathbf{e}_1 = \mathbf{e}$  and with  $\mathbf{z}_0, \mathbf{z}_1$ 
  - ▶ **P** already has  $\mathbf{z}_1$  and can compute  $\mathbf{z}_0$  using the witness
- ▶ Soundness
  - ▶ If **P** doesn't know a witness for  $\mathbf{x}_1$ , he can only answer for a single  $\mathbf{e}_1$
  - ▶ This means that  $\mathbf{e}$  defines a single challenge  $\mathbf{e}_0$ , like in a regular proof

# OR of Many Statements

---

- ▶ Prove **k out of n** statements  $x_1, \dots, x_n$ 
  - ▶ **A** = set of indices that prover knows how to prove; the other indices are denoted as **B**.  $|A|=k$ .  $|B|=n-k$ .
  - ▶ Use secret sharing with threshold  $n-k+1$
  - ▶ Field elements  $1, 2, \dots, n$ . Polynomial **f** of degree  $n-k$
  - ▶ Share for party **P<sub>i</sub>**: **f(i)**
- ▶ Prover
  - ▶ For every  $i \in \mathbf{B}$ , prover generates  $(\mathbf{a}_i, \mathbf{e}_i, \mathbf{z}_i)$  using SIM
  - ▶ For every  $j \in \mathbf{A}$ , prover generates  $\mathbf{a}_j$  as in protocol
  - ▶ Prover sends  $(\mathbf{a}_1, \dots, \mathbf{a}_n)$

# OR of Many Statements

---

- ▶ Prover sent  $(\mathbf{a}_1, \dots, \mathbf{a}_n)$
- ▶ Verifier sends a random field element  $e \in F$
- ▶ Prover finds the (only) polynomial  $f$  of degree  $n-k$  passing through all  $(i, e_i)$  and  $(0, e)$  (for  $i \in B$ )
  - ▶ The prover computes  $e_j = f(j)$  for every  $j \in A$
  - ▶ The prover computes  $\mathbf{z}_j$  as in the protocol, based on transcript  $\mathbf{a}_j, e_j$
- ▶ Soundness follows because there are  $|F|$  possible vectors and the prover can only answer one

# General Compound Statements

---

- ▶ This can be generalized to any monotone formula (meaning that the formula contains AND/OR but no negations)
  - ▶ See Cramer, Damgård, Schoenmakers, Proofs of partial knowledge and simplified design of witness hiding protocols, CRYPTO'94.

# ZK from Sigma Protocols

---

- ▶ A tool: **commitment schemes**
- ▶ Enables to commit to a chosen value while keeping it secret, with the ability to reveal the committed value later.
- ▶ A commitment has two properties:
  - ▶ **Binding:** After sending the commitment, it is impossible for the committing party to change the committed value.
  - ▶ **Hiding:** By observing the commitment, it is impossible to learn what is the committed value. (Therefore the commitment process must be probabilistic.)
- ▶ It is possible to have unconditional security for any one of these properties, but not for both.

# ZK from Sigma Protocols

---

- ▶ The basic idea
  - ▶ Have  $V$  first commit to its challenge  $e$  using a perfectly-hiding commitment
- ▶ The protocol
  - ▶  $P$  sends the first message  $\alpha$  of the commit protocol
  - ▶  $V$  sends a commitment  $c = \mathbf{Com}_\alpha(e; r)$
  - ▶  $P$  sends a message  $a$
  - ▶  $V$  opens the commitment by sending  $(e, r)$
  - ▶  $P$  checks that  $c = \mathbf{Com}_\alpha(e; r)$  and if yes sends a reply  $z$
  - ▶  $V$  accepts based on  $(x, a, e, z)$

# ZK from Sigma Protocols

---

- ▶ **Soundness:**

- ▶ The perfectly hiding commitment reveals nothing about  $\mathbf{e}$  and so soundness is preserved

- ▶ **Zero knowledge**

- ▶ In order to simulate:

- ▶ Send  $\mathbf{a}'$  generated by the simulator, for a random  $\mathbf{e}'$
- ▶ Receive  $\mathbf{V}$ 's decommitment to  $\mathbf{e}$
- ▶ Run the simulator again with  $\mathbf{e}$ , rewind  $\mathbf{V}$  and send  $\mathbf{a}$ 
  - Repeat until  $\mathbf{V}$  decommits to  $\mathbf{e}$  again
- ▶ Conclude by sending  $\mathbf{z}$

- ▶ **Analysis...**

# Pedersen Commitments

---

- ▶ Highly efficient perfectly-hiding commitments (two exponentiations for string commit)
  - ▶ **Parameters:** generator  $g$ , order  $q$
  - ▶ **Commit protocol** (commit to  $x$ ):
    - ▶ Receiver chooses random  $k$  and sends  $h=g^k$
    - ▶ Sender sends  $c=g^r h^x$ , for random  $r$
  - ▶ **Hiding:**
    - ▶ For every  $x,y$  there exist  $r,s$  s.t.  $r+kx = s+ky \pmod q$
  - ▶ **Binding:**
    - ▶ If sender can open commitment in two ways, i.e. find  $(x,r),(y,s)$  s.t.  $g^r h^x = g^s h^y$ , then  $k = (r-s)/(y-x) \pmod q$

# Efficiency of ZK

---

- ▶ Using Pedersen commitments, the entire DLOG proof costs only 5 additional group exponentiations
  - ▶ In Elliptic curve groups this is very little

# ZKPOK from Sigma Protocols

---

- ▶ Is the previous protocol a proof of knowledge?
  - ▶ It seems not to be
  - ▶ The extractor for the Sigma protocol needs to obtain two transcripts with the same  $\mathbf{a}$  and different  $\mathbf{e}$ 
    - ▶ The prover may choose its first message  $\mathbf{a}$  differently for every commitment string.
    - ▶ But in this protocol the prover sees a commitment to  $\mathbf{e}$  before sending  $\mathbf{a}$ .
    - ▶ So if the extractor changes  $\mathbf{e}$ , the prover changes  $\mathbf{a}$

# ZKPOK from Sigma Protocols

---

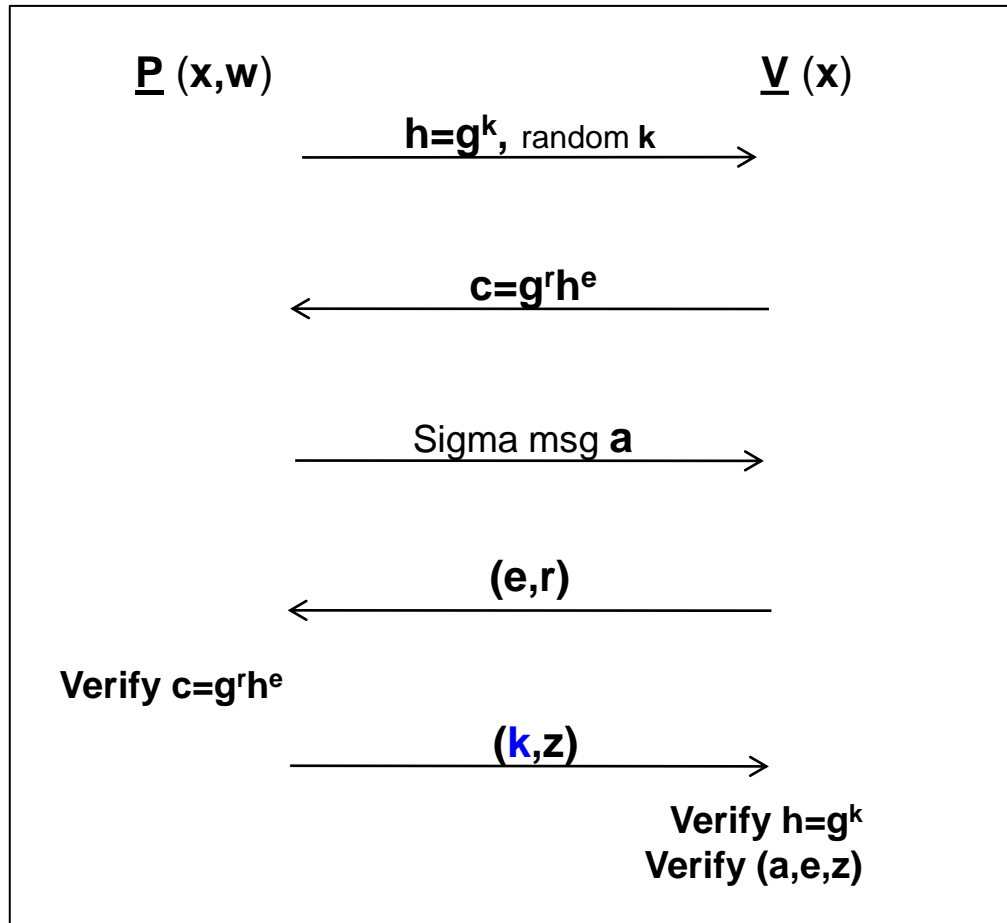

- ▶ **Solution: use a trapdoor (equivocal) commitment scheme**
  - ▶ Given a trapdoor, it is possible to open the commitment to any value
- ▶ **Pedersen has this property – given the discrete log  $k$  of  $h$ , can decommit to any value**
  - ▶ Commit to  $x$ :  $c = g^r h^x$
  - ▶ To decommit to  $y$ , find  $s$  such that  $r+kx = s+ky$
  - ▶ This is easy if  $k$  is known: compute  $s = r+k(x-y) \bmod q$

# ZKPOK from Sigma Protocols

---

- ▶ **The basic idea**
  - ▶ Have **V** first commit to its challenge **e** using a perfectly-hiding trapdoor (equivocal) commitment
- ▶ **The protocol**
  - ▶ **P** sends the first message  $\alpha$  of the commit protocol (e.g., including  $h$  in the case of Pedersen commitments).
  - ▶ **V** sends a commitment  $c = \mathbf{Com}_\alpha(\mathbf{e}; \mathbf{r})$
  - ▶ **P** sends a message **a**
  - ▶ **V** sends  $(\mathbf{e}, \mathbf{r})$
  - ▶ **P** checks that  $c = \mathbf{Com}_\alpha(\mathbf{e}; \mathbf{r})$  and if yes sends the **trapdoor** for the commitment and **z**
  - ▶ **V** accepts if the **trapdoor** is correct and  $(\mathbf{x}, \mathbf{a}, \mathbf{e}, \mathbf{z})$  is accepting

# ZKPOK from Sigma Protocols

# ZKPOK from Sigma Protocols

---

- ▶ Why does this help?
  - ▶ **Zero-knowledge** remains the same
  - ▶ **Extraction:** after verifying the proof once, the extractor obtains  $\mathbf{k}$  and can rewind back to the decommitment of  $\mathbf{c}$  and send any  $(\mathbf{e}', \mathbf{r}')$
- ▶ **Efficiency:**
  - ▶ Just 6 exponentiations (very little)

# ZK and Sigma Protocols

---

- ▶ We typically want zero knowledge, so why bother with sigma protocols?
  - ▶ There are many useful general transformations
    - ▶ E.g., parallel composition, compound statements
    - ▶ The ZK and ZKPOK transformations can be applied on top of the above, so obtain transformed ZK
  - ▶ It is **much harder** to prove ZK than Sigma
    - ▶ ZK – distributions and simulation
    - ▶ Sigma: only HVZK and special soundness

# Using Sigma Protocols and ZK

---

- ▶ Prove that the El Gamal encryption  $(u,v)$  under public-key  $(g,h)$  is to the value  $m$ 
  - ▶ By the definition of El Gamal encryption:  $u=g^r$ ,  $v=h^r \cdot m$
  - ▶ Thus  $(g,h,u,v/m)$  is a DH tuple
  - ▶ So, given  $(g,h,u,v,m)$ , just prove that  $(g,h,u,v/m)$  is a DH tuple

# Another application: Efficient Coin Tossing

---

- ▶  $P_1$  chooses a random  $x$ , sends  $(g, h, g^r, h^r x)$
- ▶  $P_1$  ZK-proves that it knows the encrypted value
  - ▶ Suffices to prove that it knows the discrete log of  $h$
- ▶  $P_2$  chooses a random  $y$  and sends to  $P_1$
- ▶  $P_1$  sends  $x$  (without decommitting)
- ▶  $P_1$  ZK-proves that encrypted value was  $x$
- ▶ Both parties output  $x+y$
  
- ▶ Cost:  $O(l)$  exponentiations

# Prove Knowledge of Committed Value

---

- ▶ Relation:  $((h,c),(x,r)) \in R$  iff  $c = g^r h^x$
- ▶ Sigma protocol:
  - ▶ P chooses random  $\alpha, \beta$  and sends  $\mathbf{a} = \mathbf{h}^\alpha \mathbf{g}^\beta$
  - ▶ V sends a random  $\mathbf{e}$
  - ▶ P sends  $\mathbf{u} = \alpha + \mathbf{e}x, \mathbf{v} = \beta + \mathbf{e}r$
  - ▶ V checks that  $\mathbf{h}^{\mathbf{u}} \mathbf{g}^{\mathbf{v}} = \mathbf{a} \mathbf{c}^{\mathbf{e}}$
- ▶ Completeness:
  - ▶  $\mathbf{h}^{\mathbf{u}} \mathbf{g}^{\mathbf{v}} = \mathbf{h}^{\alpha + \mathbf{e}x} \mathbf{g}^{\beta + \mathbf{e}r} = \mathbf{h}^\alpha \mathbf{g}^\beta (\mathbf{h}^x \mathbf{g}^r)^{\mathbf{e}} = \mathbf{a} \mathbf{c}^{\mathbf{e}}$

# Pedersen Commitment Proof

## ▶ Special soundness:

- ▶ Given  $(a, e, u, v), (a, e', u', v')$ , we have  $h^u g^v = ac^e, h^{u'} g^{v'} = ac^{e'}$

Thus,  $h^u g^v c^{-e} = h^{u'} g^{v'} c^{-e'}$

and  $h^{u-u'} g^{v-v'} = c^{e-e'}$

- ▶ Conclude:  $x = (u-u')(e-e')$  and  $r = (v-v')(e-e')$

## ▶ Special HVZK

- ▶ Given  $(g, h, h, c)$  and  $e$ , choose random  $u, v$  and compute  $a = h^u g^v c^{-e}$

# Proof of Pedersen Value

---

- ▶ Prove that the Pedersen committed value is  $x$
- ▶ Relation:  $((h,c,x),(r)) \in R$  iff  $c = g^r h^x$ 
  - ▶ Observe:  $ch^{-x} = g^r$
  - ▶ Conclusion: just prove that you know the discrete log of  $ch^{-x}$
- ▶ Application: statistical coin tossing
