# Advanced Topics in Cryptography

# Lecture 1

# **Benny Pinkas**

Advanced Topics in Cryptography February 26, 2013

### Administrative Details

- Grade
  - Based on
    - homeworks (might include a final take home exam)
    - Participation in class
- Email: <u>benny@pinkas.net</u>
- Web page: <u>http://www.pinkas.net/courses/atc/index.html</u>
- Goal: Learn a selection of advanced topics in cryptography

### Course Outline

#### Course Outline

- Cryptography is more than just encryption/signatures:
  - Oblivious transfer, secure computation.
  - Privacy preserving database operations: Private information retrieval (PIR), computing intersections, keyword search.
  - Search on encrypted data.
- Advanced topics in encryption:
  - Encryption with chosen-ciphertext security.
  - Homomorphic encryption.
  - Pairing based cryptography. Identity based encryption (IBE). Signature schemes.
  - Broadcast encryption.
  - Side channel attacks.

# Today Lecture: Oblivious Transfer

An application: computing "AND" privately

- Two players, PI and P2, have *binary* inputs *a* and *b*.
- They wish to compute a AND b without revealing any other information about their inputs.
- If PI's input is a=0, and he learns that (a AND b) = 0, he does not learn whether P2's input is 0 or 1.
- This is the first example of "secure computation" that we will learn
- Applications?
  - dating

# 1-out-of-2 Oblivious Transfer

- Two players: sender and receiver.
  - Sender has two inputs,  $x_0, x_1$ .
  - Receiver has an input  $j \in \{0, I\}$ .

#### • Output:

- Receiver learns x<sub>i</sub> and nothing else.
- Sender learns nothing about j.
- Depending on the OT variant, the inputs x<sub>0</sub>,x<sub>1</sub> could be strings or bits.
- Suppose that we have a construction of bit OT, how can we solve the AND computation problem?

### Computing "AND" Privately using OT

- P1 plays the sender's part, P2 is the receiver.
  - > P1 sets the sender's inputs to be  $x_0=0$ ,  $x_1=a$ .

▶ P2 sets the receiver's input to be *j*=*b*.

- They run an OT protocol, and P2 sends the final answer to P1.
- The output is  $(1-j)\cdot x_0+j\cdot x_1 = (1-b)\cdot 0+b\cdot a = a\cdot b$ .
- Privacy (hand-waving):
  - If b=0 then the result that P2 obtains in the OT protocol is always 0 and does not reveal anything about a.
  - If b=1 then the result obtained in the OT protocol is equal to a, but it is also equal to a·b which is the legitimate output of P2.

The Dating Problem

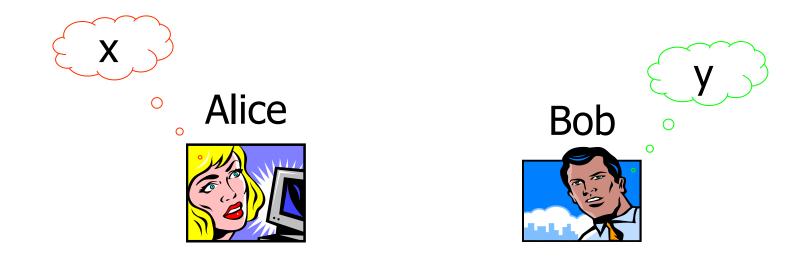

### Is a=b?

### Leak no other information!

Advanced Topics in Cryptography February 26, 2013

The Millionaires Problem

# Whose value is greater? Leak no other information!

Advanced Topics in Cryptography February 26, 2013

#### Ideal Solution for the Secure Computation Problem

What properties would we want of secure computation?

- Privacy: No party should learn anything more than its prescribed output (and anything derived from it).
- Correctness: The output of all parties is correct.
- Independence of inputs: Corrupted parties must choose their inputs independently of the honest parties' inputs. (Think about auctions.)
- Fairness: Corrupted parties receive their outputs if and only if the honest parties also receive their outputs. (Think about signing contracts.)

A protocol is secure if it emulates the ideal solution (the participants do not learn any information that they do not learn in the ideal model)

OR

For any adversary there is a comparable one working in the Ideal Model with *similar* output

### Security definitions

- We must <u>first</u> specify the power of the adversaries.
- Semi-honest vs. malicious adversaries:
  - Semi-honest (honest but curious) adversaries follow the protocol, but might try to learn additional information from the messages they receive during protocol execution.
  - Malicious adversaries might behave arbitrarily.
  - For instance, if the protocol requires PI to send to P2 a random number z, a malicious PI might define z by choosing a random y and defining z=Enc(y).
- Can now define what it means for an OT protocol to be secure. These definitions can be applied to both semihonest and malicious adversaries.

### Security definitions: comparison to the ideal model

- Must state what it means to learn nothing but the output of the protocol.
  - Intuitively, a protocol is secure if whatever can be computed by a party participating in the protocol can be computed based on its input and output only.

### Comparison to the ideal model

- Ideal implementation:
  - There is a trusted third party (TTP). It receives the inputs from the parties, computes the output, and sends it to the parties.
  - For OT: the TTP receives x<sub>0</sub>, x<sub>1</sub> from the sender, and j from the receiver. It sends x<sub>i</sub> to the receiver.
  - For AND:TTP receives *a*,*b* from PI,P2, and returns *a* AND *b*.
- Security comparison with the ideal model
  - Given a player's interaction with the TTP, it is possible to simulate the interaction it has in the protocol.

### Security of Computing "AND" Privately using OT

Privacy against a corrupt P2: (against semi-honest adversaries)

- Show here that P2 does not learn more than the "AND" result.
- Must show that given the output of the "AND" function, it is possible to provide P2 with its "view" in the "AND" protocol (namely, the output of the OT).
- Proof: We receive the output of the "AND" function and can simulate the input of the sender (PI) in the OT protocol. Therefore P2's output in the OT protocol is a function of the "AND" result alone.
  - Our input: a AND b, and P2's input b.
  - We set  $x_0=0, x_1=a$  AND b.
  - The output of the protocol is as in the original protocol.
- How can we show a similar argument showing that PI does not learn more than the "AND" result?

### Security of Computing "AND" Privately using OT

- Privacy against a corrupt PI: (against semi-honest adversaries)
  - We show that PI does not learn more than the "AND" result.
  - Proof: Recall that P2 is the receiver in the OT. After receiving the output of the OT it sends it to P1.
  - We receive the output of the "AND" function and construct the input of the receiver in the OT protocol. Therefore PI's output in the OT protocol is a function of the "AND" result.
    - Our input: a AND b, and PI's input a.
    - We set the receiver's input to be j=a AND b.
    - ▶ PI's input to the OT is, as in the original protocol, (0,a).
    - If (a AND b) is 0 then the output of the protocol is 0; if (a AND b) is
       I the output of the protocol is a (and in this case it holds that a=1).

      Therefore the output is as in the original protocol.

Constructions of OT

- There is no OT protocol which provides unconditional security for both parties.
- Namely, information theoretic security which does not depend on any computation assumption (just like a onetime-pad).
- We show this by showing that there is no AND protocol which provides unconditional security for both parties

### Impossibility of achieving OT with unconditional security

- Suppose that there is an AND protocol (between P<sub>1</sub> and P<sub>2</sub>, with inputs a and b) with <u>unconditional</u> security.
  - Such a protocol could be constructed from an OT which has unconditional security.
- Let T be a transcript of all messages sent in the protocol.
- The parties use random inputs R<sub>1</sub> and R<sub>2</sub>.
  Given these inputs the transcript T is a deterministic function.

## Impossibility of achieving OT with unconditional security

- In a certain execution with P<sub>1</sub>'s input a=0, the protocol has transcript T and output "0".
  - If b=0, then  $P_2$  must not learn  $P_1$ 's input.
  - Therefore  $\exists$  an R'<sub>1</sub> s.t. if P<sub>1</sub> has inputs a=1 and R'<sub>1</sub>, the protocol would have produced the same transcript T.
  - If b=1, then output is 0. Therefore there is no R"<sub>1</sub> s.t. the protocol has transcript T for a P<sub>1</sub> input of a=1 (this is because the output of the protocol in this case is "1").

#### P<sub>1</sub> can therefore

- search over all possible values for R<sub>1</sub> and check if running them with input a=1 results in transcript T.
- If there is such an  $R_1$  then it concludes that b=0.
