

Introduction to Cryptography

Lecture 3

DES

Meet in the middle attack

Differential cryptanalysis

Message authentication

Benny Pinkas

Books

- Open University book in Hebrew (based on Stinson's book)
- Lecture notes from Bar Ilan
<http://www.cs.biu.ac.il/~lindell/89-656/main-89-656.html>

Feistel Networks

- Encryption:
- *Input:* $P = L_{i-1} \parallel R_{i-1}$. $|L_{i-1}| = |R_{i-1}|$
 - $L_i = R_{i-1}$
 - $R_i = L_{i-1} \oplus F(K_i, R_{i-1})$
- Decryption?
- No matter which function is used as F , we obtain a permutation (i.e., F is reversible).

DES (Data Encryption Standard)

- A Feistel network encryption algorithm:
 - How many rounds?
 - How are the round keys generated?
 - What is F?
- DES (Data Encryption Standard)
 - Designed by IBM and the NSA, 1977.
 - 64 bit input and output
 - 56 bit key
 - 16 round Feistel network
 - Each round key is a 48 bit subset of the key
- Throughput \approx software: 10Mb/sec, hardware: 1Gb/sec (in 1991!).
- Criticized for unpublished design *decisions* (designers did not want to disclose differential cryptanalysis).
- Linear cryptanalysis: about 2^{40} known plaintexts

DES diagram (Data Encryption Standard)

Initial permutation:

- not secret
- makes implementations in software less efficient

DES F functions

How much effort can be invested in an attack?

- Computation overhead:
 - 2^{56} computation was demonstrated to be feasible.
 - Moore's Law: computation speed doubles every 1.5 years.
 - Attacker can use a network of machines (over the Internet?)
 - 2^{80} is considered to be the lower end of "infeasible"
 - Brute force attack on DES: 2^{56}
 - Anything more efficient is considered a "break"
- Memory:
 - Terabyte = 2^{43} bits
 - 2^n memory is probably less feasible than 2^n computation

Double DES

- DES is out of date due to brute force attacks on its short key (56 bits)
- Why not apply DES twice with two keys?
 - Double DES: $\text{DES}_{k1,k2} = E_{k2}(E_{k1}(m))$
 - Key length: 112 bits
- But, double DES is susceptible to a meet-in-the-middle attack, requiring $\approx 2^{56}$ operations and storage.
 - Compared to brute force attack, requiring 2^{112} operations and $O(1)$ storage.

Meet-in-the-middle attack

- Meet-in-the-middle attack
 - $c = E_{k_2}(E_{k_1}(m))$
 - $D_{k_2}(c) = E_{k_1}(m)$
- The attack:
 - Input: (m, c) for which $c = E_{k_2}(E_{k_1}(m))$
 - For every possible value of k_1 , generate and store $E_{k_1}(m)$
 - For every possible value of k_2 , check if $D_{k_2}(c)$ is in the table
 - Might obtain several options for (k_1, k_2) . Check them or repeat the process again with a new (m, c) pair.
- The attack is applicable to any iterated cipher

Meet-in-the-middle attack

- The plaintext and the ciphertext are 64 bits long
- The key is 56 bits long
- Suppose that we are given two plaintext-ciphertext pairs (m, c) (m', c')
- The attack looks for k_1, k_2 , such that $D_{k_2}(c) = E_{k_1}(m)$ and $D_{k_2}(c') = E_{k_1}(m')$
- The correct value of k_1, k_2 satisfies both equalities
- There are 2^{112} (actually $2^{112}-1$) other values for k_1, k_2 .
- Each one of these satisfies the equalities with probability 2^{-128}
- The probability that there exists one or more of these other pairs of keys, which satisfy both equalities, is bounded from above by $2^{112-128} = 2^{-16}$.

Triple DES

- $3DES_{k_1, k_2} = E_{k_1}(D_{k_2}(E_{k_1}(m)))$
- Why use $Enc(Dec(Enc()))$?
 - Backward compatibility: setting $k_1=k_2$ is compatible with single key DES
- Only two keys
 - Effective key length is 112 bits
 - Why not use three keys? There is a meet-in-the-middle attack with 2^{112} operations
- 3DES provides good security. Widely used. Less efficient.

Differential Cryptanalysis of DES

DES diagram:

S-boxes

Differential Cryptanalysis [Biham-Shamir 1990]

- The first attack to reduce the overhead of breaking DES to below exhaustive search
- Very powerful when applied to other encryption algorithms
- Depends on the structure of the encryption algorithm
- Observation: all operations except for the s-boxes are linear
- Linear operations:
 - $a = b \oplus c$
 - a = the bits of b in (known) permuted order
- Linear relations can be exposed by solving a system of linear equations

A Linear F in a Feistel Network?

- Suppose $F(R_{i-1}, K_i) = R_{i-1} \oplus K_i$
 - Namely, that F is linear
- Then $R_i = L_{i-1} \oplus R_{i-1} \oplus K_i$
 $L_i = R_{i-1}$
- Write L_{16}, R_{16} as linear functions of L_0, R_0 and K.
 - Given L_0, R_0 and L_{16}, R_{16} Solve and find K.
- F must therefore be non-linear.
- F is the only source of non-linearity in DES.

DES F functions

Differential Cryptanalysis

- The S-boxes are non-linear
- We study the differences between two encryptions of two different plaintexts
- Notation:
 - The plaintexts are P and P^*
 - Their difference is $dP = P \oplus P^*$
 - Let X and X^* be two intermediate values, for P and P^* , respectively, in the encryption process.
 - Their difference is $dX = X \oplus X^*$

The advantage of looking at XORs

- It's easy to predict the difference of the results of linear operations
- Unary operations, (e.g. P is a permutation of the bits of X)
 - $dP(x) = P(x) \oplus P(x^*) = P(x \oplus x^*) = P(dx)$
- XOR
 - $d(x \oplus y) = (x \oplus y) \oplus (x^* \oplus y^*) = (x \oplus x^*) \oplus (y \oplus y^*) = dx \oplus dy$
- Mixing the key
 - $d(x \oplus k) = (x \oplus k) \oplus (x^* \oplus k) = x \oplus x^* = dx$
 - The result here is key independent (the key disappears)

Differences and S-boxes

- S-box: a function (table) from 6 bit inputs to 4 bit output
- X and X^* are inputs to the same S-box, and we know their difference $dX = X \oplus X^*$.
- $Y = S(X)$
- When $dX=0$, $X=X^*$, and therefore $Y=S(X)=S(X^*)=Y^*$, and $dY=0$.
- When $dX \neq 0$, $X \neq X^*$ and we don't know dY for sure, but we can investigate its distribution.
- For example,

Distribution of Y' for $S1$

- $dX=110100$
- $2^6=64$ input pairs, $\{ (000000,110100), (000001,110101), \dots \}$
- For each pair compute xor of outputs of $S1$
- E.g., $S1(000000)=1110$, $S1(110100)=1001$. $dY=0111$.
- Table of frequencies of each dY :

0000	0001	0010	0011	0100	0101	0110	0111
0	8	16	6	2	0	0	12
1000	1001	1010	1011	1100	1101	1110	1111
6	0	0	0	0	8	0	6

Differential Probabilities

- The probability of $dX \Rightarrow dY$ is the probability that a pair of difference dX results in a pair of difference dY (for a given S-box).
- Namely, the entries in the table divided by 64.
- Differential cryptanalysis uses entries with large values
 - $dX=0 \Rightarrow dY=0$
 - Entries with value 16/64.

Warmup

Inputs: L_0R_0 , $L_0^*R_0^*$, s.t. $R_0=R_0^*$.
Namely, inputs whose xor is $dL_0 0$

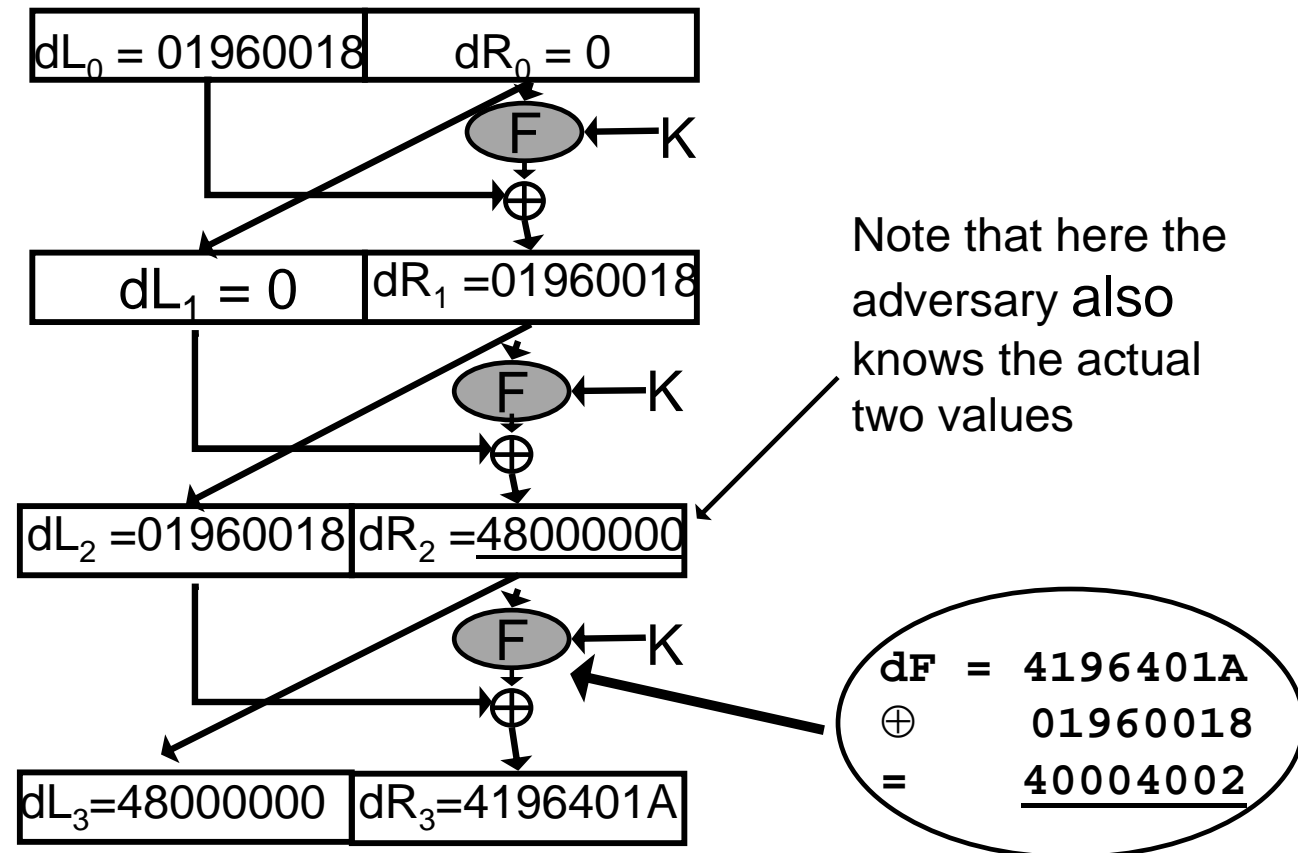

3 Round DES

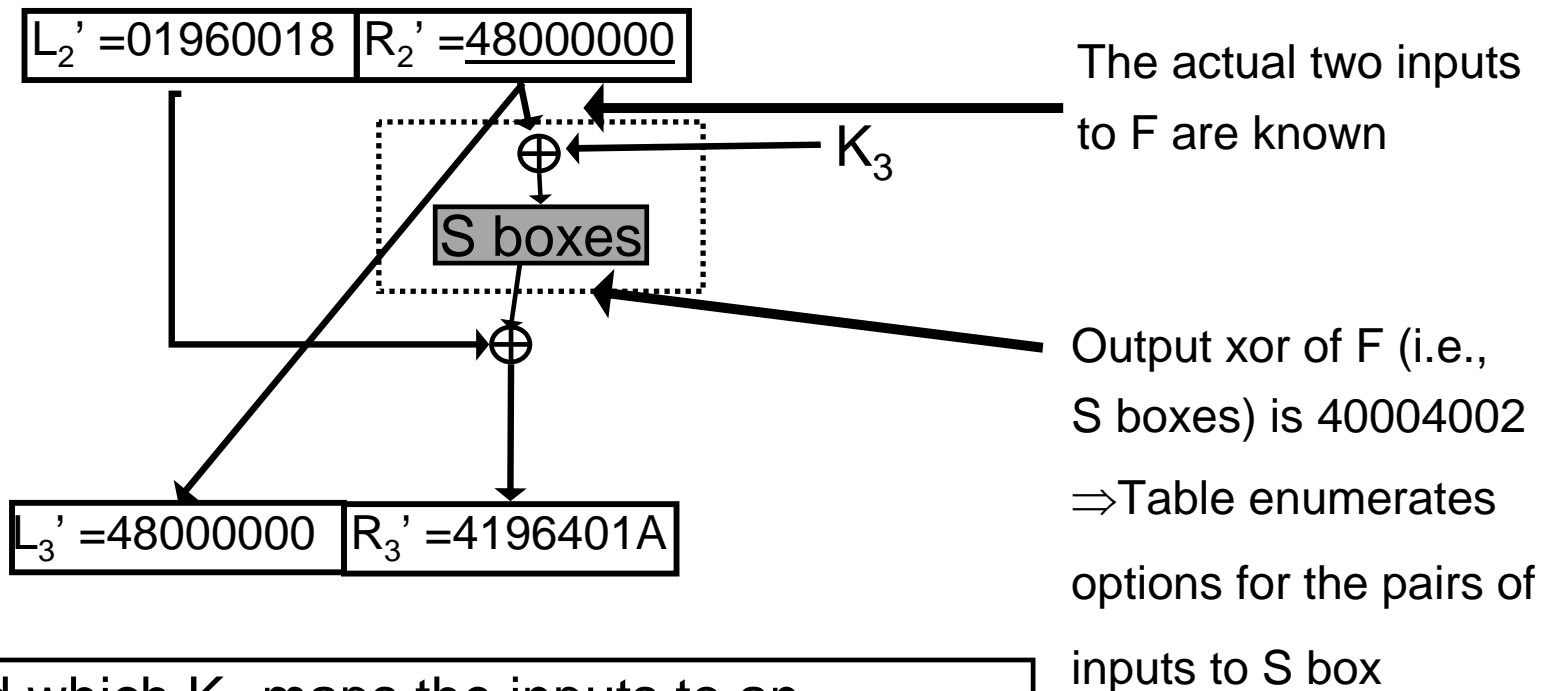

The attacker knows the two plaintext/ciphertext pairs, and therefore also their differences

Intermediate differences equal to plaintext/ciphertext differences

Finding K

Find which K_3 maps the inputs to an s-box input pair that results in the output pair!

DES with more than 3 rounds

- Carefully choose pairs of plaintexts with specific xor, and determine xor of pairs of intermediate values at various rounds.
- E.g., if $dL_0 = 40080000_x$, $dR_0 = 04000000_x$
Then, with probability $\frac{1}{4}$, $dL_3 = 04000000_x$, $dR_3 = 40080000_x$
- 8 round DES is broken given 2^{14} chosen plaintexts.
- 16 round DES is broken given 2^{47} chosen plaintexts...

AES (Advanced Encryption Standard)

- Design initiated in 1997 by NIST
 - Goals: improve security and software efficiency of DES
 - 15 submissions, several rounds of public analysis
 - The winning algorithm: Rijndael
- Input block length: 128 bits
- Key length: 128, 192 or 256 bits
- Multiple rounds (10, 12 or 14), but does not use a Feistel network

Data Integrity, Message Authentication

- Challenge: an *active* adversary might change messages exchanged between Alice and Bob

- Authentication is orthogonal to secrecy. A relevant challenge regardless of whether encryption is applied.

One Time Pad

- OTP is a perfect cipher, yet provides no authentication
 - Plaintext $x_1x_2\dots x_n$
 - Key $k_1k_2\dots k_n$
 - Ciphertext $c_1=x_1\oplus k_1, c_2=x_2\oplus k_2, \dots, c_n=x_n\oplus k_n$
- Adversary changes, e.g., c_2 to $1\oplus c_2$
- User decrypts $1\oplus x_2$
- Error-detection codes are insufficient. (For example, linear codes can be changed by the adversary, even if encrypted.)
