

# Introduction to Cryptography

## Lecture 6

Basic Number Theory,  
Diffie-Hellman Key Exchange  
El Gamal Encryption

Benny Pinkas

## Last lecture

- Basic number theory
  - Integer numbers, divisors, primes
  - Modular operations
  - Extended gcd algorithm
    - Given  $a, b$  finds  $s, t$  such that  $\gcd(a, b) = a \cdot s + b \cdot t$
    - There is no common number smaller than  $\gcd(a, b)$  which can be represented as a linear combination of  $a, b$ 
      - For example,  $a=12, b=8$ .
      - $4 = 1 \cdot 12 - 1 \cdot 8$
      - There are no  $s, t$  for which  $2 = s \cdot 12 + t \cdot 8$
  - Groups
  - Discrete log

## Groups we will use

- $Z_p^*$  Multiplication modulo a prime number  $p$ 
  - $(G, \circ) = (\{1, 2, \dots, p-1\}, \times)$
  - E.g.,  $Z_7^* = (\{1, 2, 3, 4, 5, 6\}, \times)$
- $Z_N^*$  Multiplication modulo a composite number  $N$ 
  - $(G, \circ) = (\{a \text{ s.t. } 1 \leq a \leq N-1 \text{ and } \gcd(a, N)=1\}, \times)$
  - E.g.,  $Z_{10}^* = (\{1, 3, 7, 9\}, \times)$
- A group  $G$  is cyclic if there exists a generator  $g$ , s.t.  
 $\forall a \in G, \exists i \text{ s.t. } g^i = a.$ 
  - I.e.,  $G = \langle g \rangle = \{1, g, g^2, g^3, \dots\}$
  - For example  $Z_7^* = \langle 3 \rangle = \{1, 3, 2, 6, 4, 5\}$

# The Discrete Logarithm

- Let  $G$  be a cyclic group of order  $q$ , with a generator  $g$ .
  - $\forall h \in G, \exists x \in [0, \dots, q-1]$ , such that  $g^x = h$ .
  - This  $x$  is called the discrete logarithm of  $h$  to the base  $g$ .
  - $\log_g h = x$ .
  - $\log_g 1 = 0$ , and  $\log_g(h_1 \cdot h_2) = \log_g(h_1) + \log_g(h_2) \pmod q$ .

## The Discrete Logarithm Problem and Assumption

- The discrete log problem
  - Choose  $G, g$  at random (from a certain family  $\mathcal{G}$  of groups), where  $G$  is a cyclic group and  $g$  is a generator
  - Choose a random element  $h \in G$
  - Give the adversary the input  $(G, |G|, g, h)$
  - The adversary succeeds if it outputs  $\log_g h$
- The discrete log assumption
  - There exists a family  $\mathcal{G}$  of groups for which the discrete log problem is hard
    - Namely, a polynomial adversary has negligible success probability.

## Cyclic groups of prime order

- (The order of a group  $G$  is the number of elements in the group)
- $Z_p^*$  has order  $p-1$  (and  $p-1$  is even and therefore non-prime).
- We will need to work in groups of *prime* order.
- If  $p=2q+1$ , and  $q$  is prime, then  $Z_p^*$  has a subgroup of order  $q$  (namely, a subgroup of prime order).

## Hard problems in cyclic groups of prime order

- The following problems are believed to be hard in subgroups of prime order of  $Z_p^*$  (if the subgroup is large enough)
  - The discrete log problem
  - The Diffie-Hellman problem: The input contains  $g$  and  $x, y \in G$ , such that  $x = g^a$  and  $y = g^b$  (where  $a, b$  where chosen at random). The task is to find  $z = g^{a \cdot b}$ .
  - The Decisional Diffie-Hellman problem: The input contains  $x, y \in G$ , such that  $x = g^a$  and  $y = g^b$  (and  $a, b$  where chosen at random); and a pair  $(z, z')$  where one of  $(z, z')$  is  $g^{a \cdot b}$  and the other is  $g^c$  (for a random  $c$ ). The task is to tell which of  $(z, z')$  is  $g^{a \cdot b}$ .
- Solving DDH  $\leq$  solving DH  $\leq$  solving DL
  - All believed to be hard if the size of the subgroup  $> 2^{700}$ .

## Working in $Z_p^*$

- We would like to work in a group in which the DDH assumption holds
- We show next that the DDH assumption does not hold in  $Z_p^*$ 
  - But it does hold in a subgroup of  $Z_p^*$

# Quadratic Residues

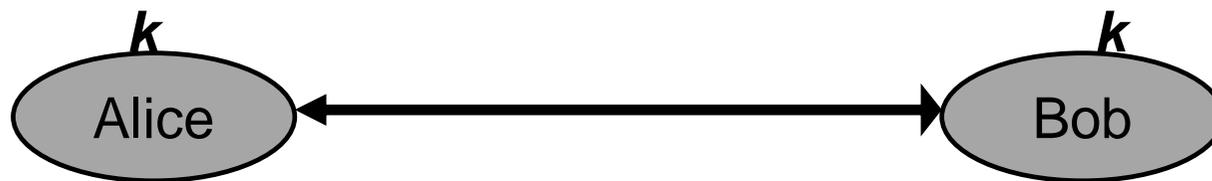

- The square root of  $x \in \mathbb{Z}_p^*$  is  $y \in \mathbb{Z}_p^*$  s.t.  $y^2 = x \pmod p$ .
- Examples:  $\text{sqrt}(2) \pmod 7 = 3$ ,  $\text{sqrt}(3) \pmod 7$  doesn't exist.
- How many square roots does  $x \in \mathbb{Z}_p^*$  have?
  - If  $a$  and  $b$  are square roots of  $x$ , then  $x = a^2 = b^2 \pmod p$ .  
Therefore  $(a-b)(a+b) = 0 \pmod p$ . Therefore either  $a = b$  or  $a = -b$  modulo  $p$ .
  - Therefore  $x$  has either 2 or 0 square roots, and is denoted as a Quadratic Residue (QR) or Non Quadratic Residue (NQR), respectively.  
There are exactly  $(p-1)/2$  QRs.
- $x^{(p-1)/2}$  is either 1 or -1 in  $\mathbb{Z}_p^*$ . (indeed,  $(x^{(p-1)/2})^2$  is always 1)
- Euler's theorem:  $x \in \mathbb{Z}_p^*$  is a QR iff  $x^{(p-1)/2} = 1 \pmod p$ .
- Legendre's symbol:
$$\left(\frac{x}{p}\right) = \begin{cases} 1 & x \text{ is a QR in } \mathbb{Z}_p^* \\ -1 & x \text{ is an NQR in } \mathbb{Z}_p^* \\ 0 & x = 0 \pmod p \end{cases}$$
- Legendre's symbol can be efficiently computed as  $x^{(p-1)/2} \pmod p$ .
- The quadratic residues form a subgroup of order  $(p-1)/2$  ( $=q$ )

## Does the DDH assumption hold in $Z_p^*$ ?

- The DDH assumption does not hold in  $Z_p^*$ 
  - Assume that both  $x=g^a$  and  $y=g^b$  are QRs in  $Z_p^*$ .
  - Then  $g^{ab}$  is also a QR, whereas a random  $g^c$  is an NQR with probability  $\frac{1}{2}$ .
- Solution: (work in a subgroup of prime order)
  - Set  $p=2q+1$ , where  $q$  is prime.
  - $\phi(Z_p^*) = p-1 = 2q$ . Therefore  $Z_p^*$  has a subgroup  $H$  of prime order  $q$ .
  - Let  $g$  be a generator of  $H$  (for example,  $g$  is a QR in  $Z_p^*$ ).
  - The DDH assumption is believed to hold in  $H$ . (The Legendre symbol is always 1.)

## Classical symmetric ciphers

- Alice and Bob share a private key  $k$ .
- System is secure as long as  $k$  is secret.
- Major problem: generating and distributing  $k$ .

## Diffie and Hellman: “New Directions in Cryptography”, 1976.

- “We stand today on the brink of a revolution in cryptography. The development of cheap digital hardware has freed it from the design limitations of mechanical computing...  
...such applications create a need for new types of cryptographic systems which minimize the necessity of secure key distribution...  
...theoretical developments in information theory and computer science show promise of providing provably secure cryptosystems, changing this ancient art into a science.”

# Diffie-Hellman

- Came up with the idea of public key cryptography

Everyone can learn Bob's public key and encrypt messages to Bob. Only Bob knows the decryption key and can decrypt.

Key distribution is greatly simplified.

- Diffie and Hellman did not have an implementation for a public key encryption system
- Suggested a method for key exchange over insecure communication lines, that is still in use today.

# Public Key-Exchange

- Goal: Two parties who do not share any secret information, perform a protocol and derive the same shared key.
- No eavesdropper can obtain the new shared key (if it has limited computational resources).
- The parties can therefore safely use the key as an encryption key.

# The Diffie-Hellman Key Exchange Protocol

- Public parameters: a group where the DDH assumption holds. For example,  $Z_p^*$  (where  $|p|= 768$  or  $1024$ ,  $p=2q+1$ ), and a generator  $g$  of a subgroup  $H \subset Z_p^*$  of order  $q$ .

- Alice:

- picks a random  $a \in [1, q]$ .
- Sends  $g^a \bmod p$  to Bob.

- Bob:

- picks a random  $b \in [1, q]$ .
- Sends  $g^b \bmod p$  to Bob.

- Computes  $k = (g^b)^a \bmod p$

- Computes  $k = (g^a)^b \bmod p$

- $K = g^{ab}$  is used as a shared key between Alice and Bob.

- DDH assumption  $\Rightarrow K$  is indistinguishable from a random key

## Diffie-Hellman: security

- A (*passive*) adversary
  - Knows  $Z_p^*$ ,  $g$
  - Sees  $g^a, g^b$
  - Wants to compute  $g^{ab}$ , or at least learn something about it
- Recall the Decisional Diffie-Hellman problem:
  - Given random  $x, y \in Z_p^*$ , such that  $x=g^a$  and  $y=g^b$ ; and a pair  $(g^{ab}, g^c)$  (in random order, for a random  $c$ ), it is hard to tell which is  $g^{ab}$ .
  - An adversary that distinguishes the key  $g^{ab}$  generated in a DH key exchange from random, can also break the DDH.
  - *Note:* it is insufficient to require that the adversary cannot compute  $g^{ab}$ .

## Diffie-Hellman key exchange: usage

- The DH key exchange can be used in any group in which the Decisional Diffie-Hellman (DDH) assumption is believed to hold.
- Currently,  $Z_p^*$  and elliptic curve groups.
- Common usage:
  - Overhead: 1-2 exponentiations
  - Usually,
    - A DH key exchange for generating a master key
    - Master key used to encrypt session keys
    - Session key is used to encrypt traffic with a symmetric cryptosystem

## An active attack against the Diffie-Hellman Key Exchange Protocol

- An active adversary Eve.
- Can read and change the communication between Alice and Bob.
- ...As if Alice and Bob communicate via Eve.

# Man-in-the-Middle: an active attack against the Diffie-Hellman Key Exchange protocol

- Alice:

- picks a random  $a \in [1, q]$ .
- Sends  $g^a \bmod p$  to Bob.

- Bob:

- picks a random  $b \in [1, q]$ .
- Sends  $g^b \bmod p$  to Alice.

Eve changes  $g^a$  to  $g^c$

Eve changes  $g^b$  to  $g^d$

- Computes  $k = (g^d)^a \bmod p$

- Computes  $k = (g^c)^b \bmod p$

| Keys:    |                  |          |
|----------|------------------|----------|
| Alice    | Eve              | Bob      |
| $g^{ad}$ | $g^{ad}, g^{bc}$ | $g^{bc}$ |

- Solution: ? (wireless usb)

# Public key encryption

- Alice publishes a *public* key  $PK_{\text{Alice}}$ .
- Alice has a *secret* key  $SK_{\text{Alice}}$ .
- Anyone knowing  $PK_{\text{Alice}}$  can encrypt messages using it.
- Message decryption is possible only if  $SK_{\text{Alice}}$  is known.
  
- Compared to symmetric encryption:
  - Easier key management:  $n$  users need  $n$  keys, rather than  $O(n^2)$  keys, to communicate securely.
- Compared to Diffie-Hellman key agreement:
  - No need for an interactive key agreement protocol. (Think about sending email...)
  
- Secure as long as we can trust the association of keys with users.

# Public key encryption

- Must have different keys for encryption and decryption.
- Public key encryption cannot provide perfect secrecy:
  - Suppose  $E_{pk}()$  is an algorithm that encrypts  $m=0/1$ , and uses  $r$  random bits in operation.
  - An adversary is given  $E_{pk}(m)$ . It can compare it to all possible  $2^r$  encryptions of 0...
- Efficiency is the main drawback of public key encryption.

## Defining a public key encryption

- The definition must include the following algorithms;
- Key generation:  $\text{KeyGen}(1^k) \rightarrow (\text{PK}, \text{SK})$  (where  $k$  is a security parameter, e.g.  $k=1000$ ).
- Encryption:  $C = E_{\text{PK}}(m)$  (E might be a randomized algorithm)
- Decryption:  $M = D_{\text{SK}}(C)$

# The El Gamal public key encryption system

- Public information (can be common to different public keys):
  - A group in which the DDH assumption holds. Usually start with a prime  $p=2q+1$ , and use  $H \subset \mathbb{Z}_p^*$  of order  $q$ . Define a generator  $g$  of  $H$ .
- Key generation: pick a random private key  $a$  in  $[1, |H|]$  (e.g.  $0 < a < q$ ). Define the public key  $h=g^a$  ( $h=g^a \bmod p$ ).
- Encryption of a message  $m \in H \subset \mathbb{Z}_p^*$ 
  - Pick a random  $0 < r < q$ .
  - The ciphertext is  $(g^r, h^r \cdot m)$ .

} Using public key alone
- Decryption of  $(s, t)$ 
  - Compute  $t/s^a$  ( $m = h^r \cdot m / (g^r)^a$ )

} Using private key

## El Gamal and Diffie-Hellman

- ElGamal encryption is similar to DH key exchange
    - DH key exchange: Adversary sees  $g^a, g^b$ . Cannot distinguish the key  $g^{ab}$  from random.
    - El Gamal:
      - A fixed public key  $g^a$ .
      - Sender picks a random  $g^r$ .
      - Sender encrypts message using  $g^{ar}$ .
- } Known to the adversary
- } Used as a key
- El Gamal is like DH where
    - The same  $g^a$  is used for all communication
    - There is no need to explicitly send this  $g^a$  (it is already known as the public key of Alice)

# The El Gamal public key encryption system

- Setting the public information
- *A large prime  $p$ , and a generator  $g$  of  $H \subset Z_p^*$  of order  $q$ .*
  - $|p| = 756$  or  $1024$  bits.
  - $p-1$  must have a large prime factor (e.g.  $p=2q+1$ )
    - Otherwise it is easy to solve discrete logs in  $Z_p^*$  (relevant also to DH key agreement)
    - Needed for the DDH assumption to hold (Legendre's symbol)
  - $g$  must be a generator of a large subgroup of  $Z_p^*$ .

# The El Gamal public key encryption system

- Encoding the message:
  - $m$  must be in the subgroup  $H$  generated by  $g$ .
  - If  $p=2q+1$ , and  $H$  is the subgroup of quadratic residues, we can map each message  $m \in \{1, \dots, (p-1)/2\}$  to the value  $m^2 \bmod p$ , which is in  $H$ .
  - Alternatively, encrypt  $m$  using  $(g^r, H(h^r) \oplus m)$ . *Decryption is done by computing  $H((g^r)^a)$ .* ( $H$  is a hash function that preserves the pseudo-randomness of  $h^r$ .)

# The El Gamal public key encryption system

- Overhead:
  - Encryption: two exponentiations; preprocessing possible.
  - Decryption: one exponentiation.
  - message expansion:  $m \Rightarrow (g^r, h^r \cdot m)$ .
- Randomized encryption
  - Must use fresh randomness  $r$  for every message.
  - Two different encryptions of the same message are different! (provides semantic security)
